*Department of Physics, University of Athens, Greece*

# Motivation

- ***Dynamical complexity detection*** for output time series of complex systems:  
one of the foremost problems in physics, etc.
- In space plasma physics: ***accurate detection of the dissimilarity between normal and abnormal states (e.g. pre-storm activity and magnetic storms)*** can vastly improve space weather diagnosis and, consequently, the mitigation of space weather hazards.

***“Modern Challenges in Nonlinear Plasma Physics”***  
***Halkidiki, 15-19/6/2009***

# Outline

- From pre-storm activity to magnetic storms: a transition described in terms of fractal dynamics
- Dynamical complexity in  $D_{st}$  time series using non-extensive Tsallis entropy

*“Modern Challenges in Nonlinear Plasma Physics”  
Halkidiki, 15-19/6/2009*

# Power-laws

- If a time series is a temporal fractal then a power law of the form:

$$S(f) \sim f^{-\beta}$$

is obeyed,

$S(f)$  - power spectral density

$f$  - frequency

$\beta$  - spectral scaling exponent, a measure of the strength of time correlations

$r$  - linear correlation coefficient: represents the fit of the time series to a power-law

***“Modern Challenges in Nonlinear Plasma Physics”***  
***Halkidiki, 15-19/6/2009***

# Wavelets

- The wavelet transform is useful for the *Dst* time series because *Dst* is non-stationary and has a time-varying frequency content.
- The wavelet analysis technique has been applied to the *Dst* time variations in order to derive the coefficients of its power spectrum.
- The continuous wavelet transform has been used, with the Morlet wavelet as basis function.

**“Modern Challenges in Nonlinear Plasma Physics”**  
**Halkidiki, 15-19/6/2009**

# Fractal Spectral Analysis

- Hourly Dst values of year 2001
- Wavelet transform to a matrix with  $65 \times (365 \times 24)$  elements, where 65 is the number of frequencies.
- Power spectral densities are estimated in the frequency range from 2 to 128 hours using a moving window of 256 samples.
- The number of samples by which the moving window sections overlap is 255.
- Spectral parameters  $r$  and  $\beta$  were calculated for each window.

***“Modern Challenges in Nonlinear Plasma Physics”***  
***Halkidiki, 15-19/6/2009***

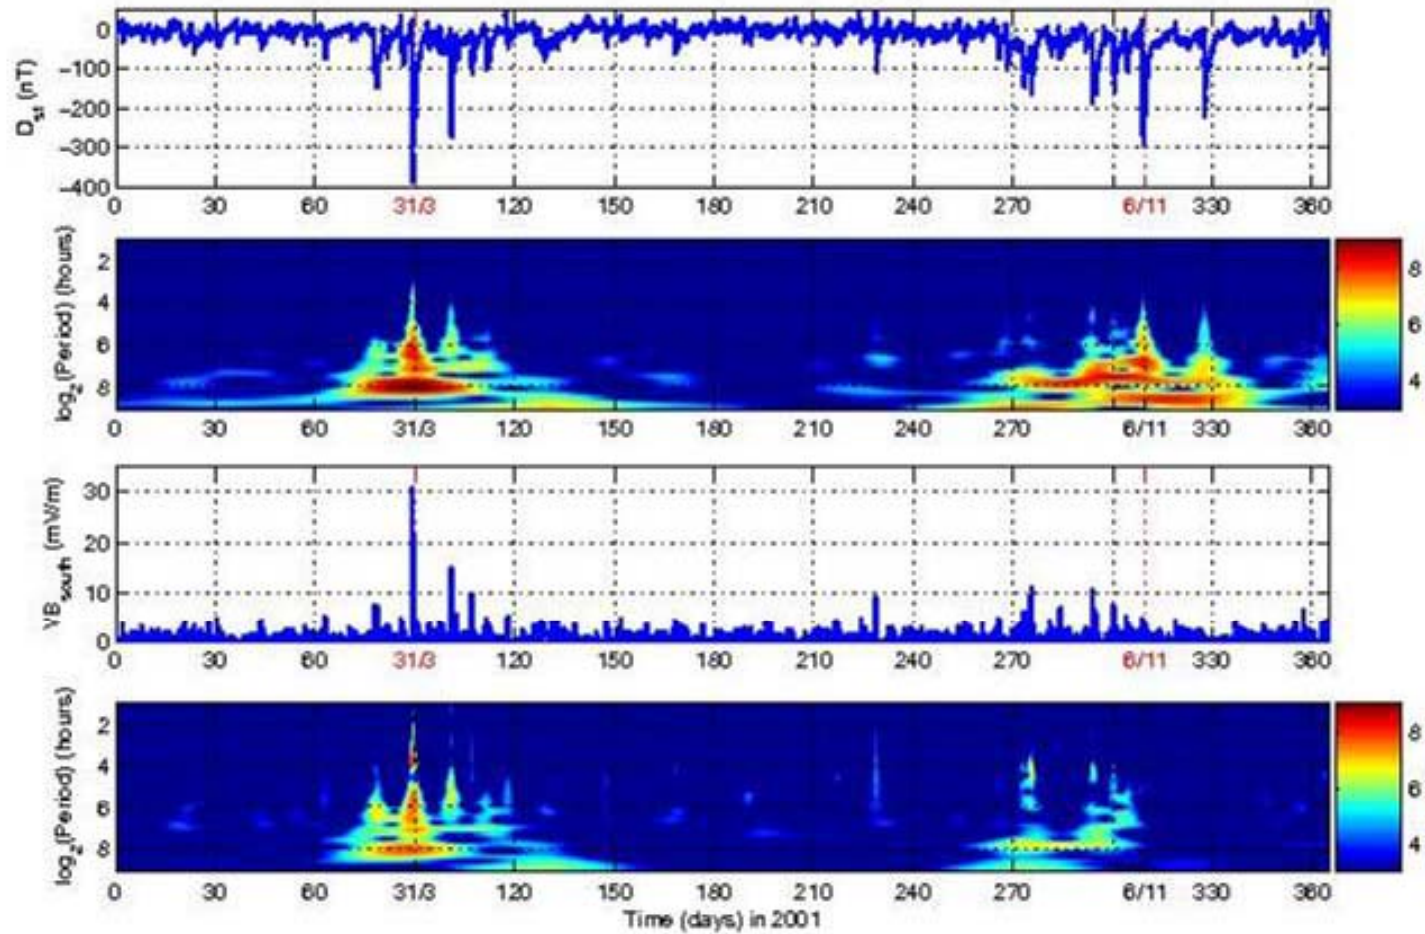

- First figure shows the  $Dst$  time series and its wavelet power spectrum
- Second figure shows the temporal evolution of its spectral parameters  $r$  and  $\beta$

# $D_{st}$ index time series

# Scaling parameters of the $D_{st}$ index

# Transition from anti-persistent to persistent behavior

$\beta=2H+1$ , where  $H$  is the Hurst exponent.

- The exponent  $H$  characterizes the ***persistent/anti-persistent*** properties of the signal. The range  $0 < H < 0.5$  ( $1 < \beta < 2$ ) during the normal period indicates ***anti-persistency***, reflecting that if the fluctuations increase in a period, they are likely to decrease in the interval immediately following and vice versa.

*“Modern Challenges in Nonlinear Plasma Physics”*  
*Halkidiki, 15-19/6/2009*

# Transition from anti-persistent to persistent behavior

- We pay attention to the fact that the time series exhibits *persistent* properties ( $0.5 < H < 1$ ,  $2 < \beta < 3$ ) close to the two MS, meaning that if the amplitude of fluctuations increases in a time interval it is likely to continue increasing in the interval immediately following.

**“Modern Challenges in Nonlinear Plasma Physics”**  
**Halkidiki, 15-19/6/2009**

# Scaling parameters of the $D_{st}$ index

# Transition from anti-persistent to persistent behavior

- $H=0.5$  ( $\beta=2$ ) suggests no correlation between the repeated increments. Consequently, this particular value has a special physical meaning:

***It marks the transition between persistent and anti-persistent behavior in the time series.***

***“Modern Challenges in Nonlinear Plasma Physics”***  
***Halkidiki, 15-19/6/2009***

# Summary

- We show that distinctive alterations in scaling parameters of  $D_{st}$  index time series occur as an intense magnetic storm approaches.
- The transition from anti-persistent to persistent behavior may indicate that the onset of an intense magnetic storm is imminent.

# Outline

- From pre-storm activity to magnetic storms: a transition described in terms of fractal dynamics
- Dynamical complexity in  $D_{st}$  time series using non-extensive Tsallis entropy

*“Modern Challenges in Nonlinear Plasma Physics”  
Halkidiki, 15-19/6/2009*

# Introduction

- The uncertainty of an open system state can be quantified by the ***Boltzmann-Gibbs (B-G) entropy***, which is the widest known uncertainty measure in statistical mechanics.
- ***B-G entropy ( $S_{B-G}$ ) cannot, however, describe non-equilibrium physical systems with large variability and multi-fractal structure such as the solar wind [Burlaga et al., 2007].***
- Inspired by multi-fractal concepts, ***Tsallis*** [1988, 1998] proposed a generalization of the B-G statistics.

***“Modern Challenges in Nonlinear Plasma Physics”***  
***Halkidiki, 15-19/6/2009***

# Extensivity

- One of the crucial properties of the  $S_{B-G}$  in the context of classical thermodynamics is **extensivity**, namely proportionality to the number of elements of the system.
- The  $S_{B-G}$  satisfies this prescription if the subsystems are statistically (quasi-) independent, or typically if the correlations within the system are essentially local. In such cases the system is called **extensive**.

**“Modern Challenges in Nonlinear Plasma Physics”**  
**Halkidiki, 15-19/6/2009**

# Tsallis entropy

- In general the situation is not of this type and correlations may be far from negligible at all scales. In such cases the  $S_{B-G}$  is **non-extensive**.
- **Tsallis** [1988, 1998] introduced an entropic expression characterized by an index  $q$  which leads to non-extensive statistics

$$S_q = k \frac{1}{q-1} \left( 1 - \sum_{i=1}^W p_i^q \right)$$

where  $p_i^q$  are the probabilities associated with the microscopic configurations,  $W$  is their total number,  $q$  is a real number, and  $k$  is Boltzmann's constant.

**“Modern Challenges in Nonlinear Plasma Physics”**  
**Halkidiki, 15-19/6/2009**

# Tsallis entropy

- The value of  $q$  is a measure of the non-extensivity of the system:  $q = 1$  corresponds to the standard, extensive, B-G statistics.
- This is the basis of the so called non-extensive statistical mechanics, which generalizes the B-G theory.

***“Modern Challenges in Nonlinear Plasma Physics”***  
***Halkidiki, 15-19/6/2009***

# Tsallis entropy and complexity

- Time variations of Tsallis entropy for a given  $q$  ( $S_q$ ) quantify the dynamic changes of the complexity of the system.
- *Lower  $S_q$  values characterize the portions of the signal with lower complexity.*
- Herein, we estimate  $S_q$  based on the concept of ***symbolic dynamics***: from the initial measurements we generate a sequence of symbols, where the dynamics of the original system has been projected [Bailin, 1989].

***“Modern Challenges in Nonlinear Plasma Physics”***  
***Halkidiki, 15-19/6/2009***

# Tsallis entropy in terms of symbolic dynamics

- **Symbolic dynamics** is based on a coarse-graining of the measurements, i.e., the original  $D_{st}$  time series of length  $N$ ,  $(X_1, X_2, \dots, X_N)$ , is projected to a symbolic time series  $(A_1, A_2, \dots, A_N)$  with  $A_n$  from a finite alphabet of  $\lambda$  letters  $(0, \dots, \lambda - 1)$ .
- After symbolization, the next step in identification of temporal patterns is the construction of symbol sequences with size  $L$ . We use the technique of lumping. Thus, we stipulate that the symbolic sequence is to be read in terms of distinct successive “blocks” of length  $L$ ,

$$A_1, A_2, \dots, A_L / A_{L+1}, \dots, A_{2L} / A_{jL+1}, \dots, A_{(j+1)L} .$$

**“Modern Challenges in Nonlinear Plasma Physics”**  
**Halkidiki, 15-19/6/2009**

# Tsallis entropy in terms of symbolic dynamics

- The simplest possible coarse graining of the  $D_{st}$  index is given by choosing a threshold  $C$  (usually the mean value of the data) and assigning the symbols “1” and “0” to the signal, depending on whether it is above or below the threshold (binary partition).
- Thus, we generate a symbolic time series from a 2-letter ( $\lambda = 2$ ) alphabet  $(0,1)$ , e.g.  $0110100110010110\dots$

**“Modern Challenges in Nonlinear Plasma Physics”**  
**Halkidiki, 15-19/6/2009**

# Tsallis entropy in terms of symbolic dynamics

- Reading the sequence by lumping of length  $L=2$ , the number of all possible kinds of blocks is  $\lambda^L = 2^2 = 4$ , namely  $00, 01, 10, 11$ .
- Thus, the required probabilities for the estimation of the Tsallis entropy  $p_{00}, p_{01}, p_{10}, p_{11}$  are the fractions of the blocks  $00, 01, 10, 11$  in the symbolic time series.

**“Modern Challenges in Nonlinear Plasma Physics”**  
**Halkidiki, 15-19/6/2009**

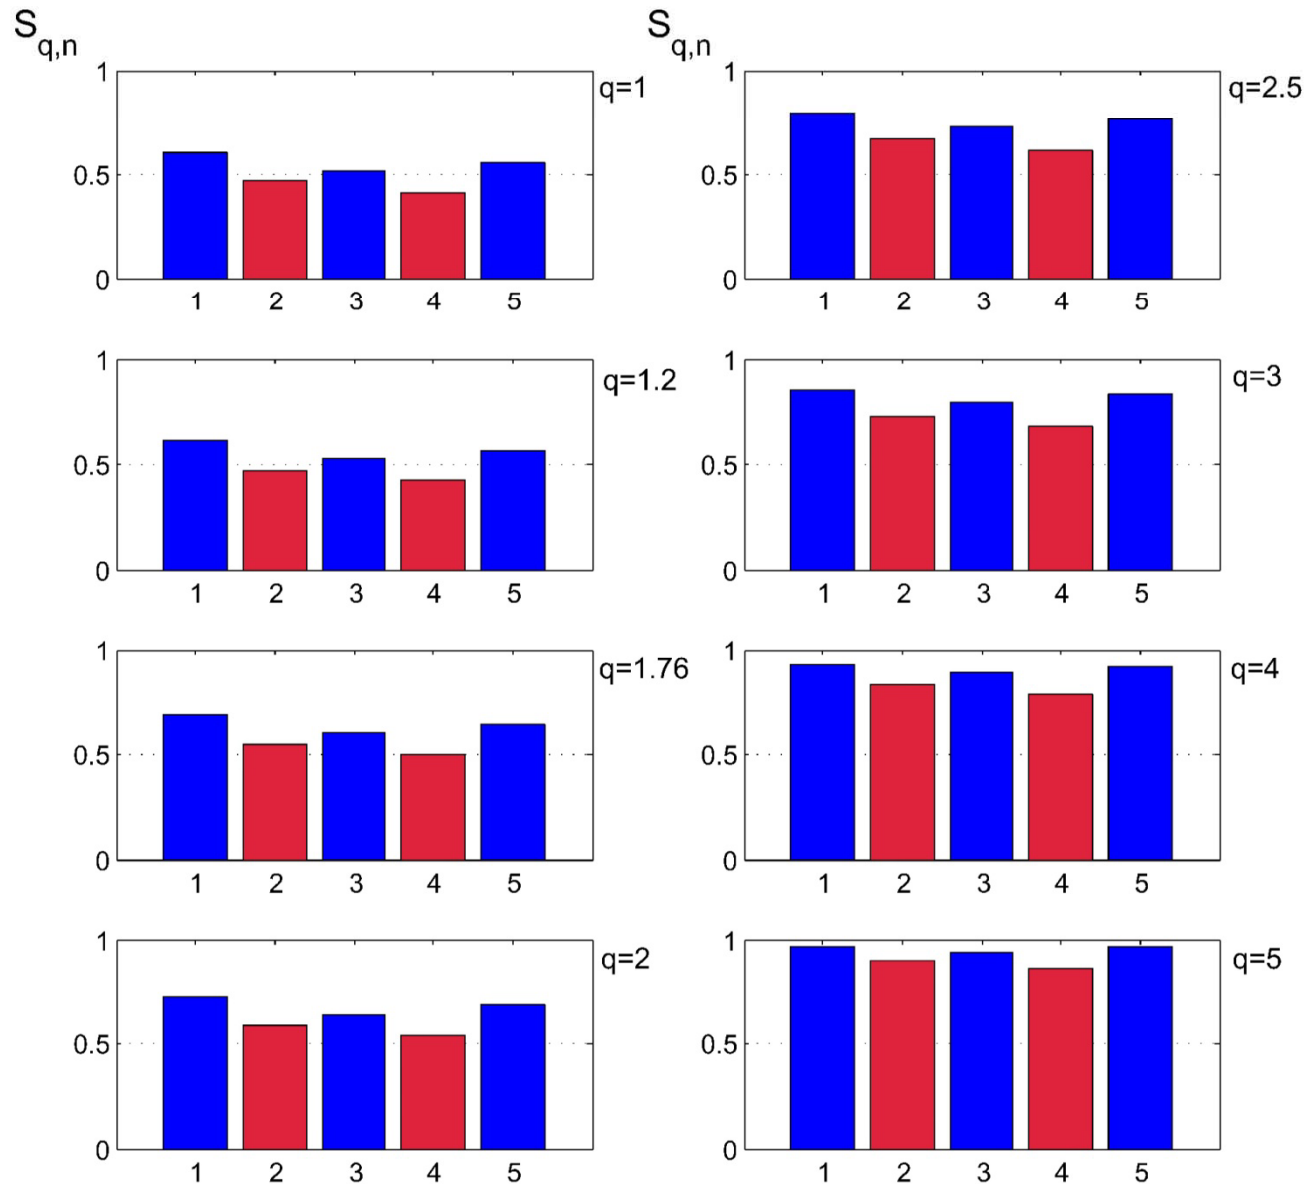

# Five time windows according to $H=0.5$

# Tsallis entropies for the 5 windows and for various values of index $q$

# Conclusions

- The Tsallis entropy sensitively shows the complexity dissimilarity among different **“physiological” (non-storm)** and **“pathological” states (magnetic storms)**. The Tsallis entropy implies the emergence of two distinct patterns:
  - (i) a pattern associated with the intense magnetic storms, which is characterized by a higher degree of organization (lower  $S_q$ ).
  - (ii) a pattern associated with non-storm periods, which is characterized by a lower degree of organization.

**“Modern Challenges in Nonlinear Plasma Physics”**  
**Halkidiki, 15-19/6/2009**

# Conclusions

- Results depend on Tsallis  $q$  value. Values in the range  $1 < q < 2$  magnify differences of  $S_q$  and therefore of complexity as MS approaches.

***“Modern Challenges in Nonlinear Plasma Physics”***  
***Halkidiki, 15-19/6/2009***

# Hurst index for same time windows

# Conclusions

- The wavelet spectral analysis in terms of Hurst exponent,  $H$ , also shows the existence of two different patterns:
- (i) a pattern associated with the intense magnetic storms, which is characterized by a fractional Brownian persistent behavior
- (ii) a pattern associated with non-storm periods, which is characterized by a fractional Brownian anti-persistent behavior.

***“Modern Challenges in Nonlinear Plasma Physics”***  
***Halkidiki, 15-19/6/2009***

# Conclusions

- We stress that the **anti-persistent time windows** correspond to the time windows of **high Tsallis entropies**, while the **persistent time windows** correspond to the time windows of **low Tsallis entropies**.
- In summary, a combination of the Tsallis entropy with the Hurst exponent can evolve into a powerful diagnostic tool for the prediction of intense magnetic storm development.
